

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

cellence of his work, without which the plates would be of much less value.

FREDERICK H. GETMAN

Historical Papers on Modern Explosives.

By GEORGE W. MACDONALD. Whittaker & Co., N. Y. 1912. Pp. 192. \$2.50 net.

When the age of the world as fixed by the most recent observers, such as Becker and Clarke, the probable length of time it has been inhabited by man, and the important part which chemistry played, both in the creation of the earth and of its inhabitants, is considered, it is an amazing thing that man was so very slow in assembling a systematized knowledge of chemistry and especially slow in recognizing those compounds which are reservoirs of energy, for though compounds of this kind, such as the nitrosubstitution compound, picric acid, discovered by Hausmann in 1788, were described in the latter part of the eighteenth century, it was not until the opening year of the nineteenth century, in which Howard discovered mercuric fulminate and demonstrated its properties, that man apparently began to realize that energy could be stored up in individual compound molecules which was ready for release at command, so that it might be employed like the bent bow, the coiled spring, the head of water, the wind, or the energy of man or animals applied through the many mechanical devices then invented, or mixtures of substances, such as gunpowders, to do work.

This new conception of a capacity with which compound molecules might be endowed was, in the middle of the nineteenth century, reinforced by Schönbein's discovery of cellulose nitrates and Sobrero's discovery of glyceryl nitrates; and the discovery and recognition of the value of molecules so constituted to mankind in the accomplishment of work has gone on with continued acceleration ever since, for masses of the mercuric fulminate, cellulose nitrates, glyceryl nitrates, alone or compounded into mixtures such as the many dynamites, smokeless powders and permissible explosives, have been put to do work in engineering projects and in military operations,

and they have, when wisely used, materially increased the resources of man in his contest with the material world in which he is placed and environed.

The period covered by MacDonald in the book under review is from 1800 to 1887 and it deals with the discovery and development of the three explosives last enumerated. This was a period of marked scientific and technical activity with regards to these bodies and much was published regarding them in widely scattered publications, some of which are now difficult of access, and because of this, and further because the earliest literature "often contains observations and experiments which are generally considered to be the results of much later investigation" the author has brought them together here after having published them as separate articles in *Arms and Explosives*.

Mr. MacDonald has not given reprints but rather condensed résumés in which he has divided single articles into several smaller ones and introduced comments of his own. Further he has drawn his material from patent literature and unpublished correspondence as well as from scientific journals, and recast or "reduced tabulated results to statements of fact." It will be seen therefore that the book is not authoritative, even to the extent that carefully supervised reprints would be, and that its usefulness is limited.

There appears a lack of proportion in the treatment since 149 out of the 192 pages are devoted to gun cotton and 98 of these to Abel's work leaving Schönbein the discoverer, and von Lenk, whose pioneer work in Austria was presented freely and in detail to the Committee of the British Association, quite in the background. In fact there is a distinctly British tendency permeating the book.

CHARLES E. MUNROE

Insect Pests of the Farm, Garden and Orchard. By E. DWIGHT SANDERSON. New York, John Wiley & Sons. 1912. \$3.00.

The author explains in the preface how his attempt to revise his former book "Insects Injurious to Staple Crops" finally resulted in
